

 "Mini Profile Card"

**Lecture 17 topics covered:** *Intro to React · JSX · Functional Components*

---

**1 . Problem Statement**

Create a tiny React application that renders several **profile cards** (think business-card-sized tiles). Each card shows:

| Field     | Example value         |
|-----------|-----------------------|
| Avatar    | remote image URL      |
| Full name | "Dana Levi"           |
| Job title | "Front-End Developer" |
| Short bio | one-sentence string   |

The data for the cards must come from a plain **JavaScript array** declared in the file (`profiles.js`). Your job is to convert that data into interactive UI using **JSX** and well-structured **functional components**.

---

**2 . Learning Goals**

| Concept                                | Where you'll practise it                            |
|----------------------------------------|-----------------------------------------------------|
| JSX syntax & embedding expressions     | Building the card layout                            |
| Functional components + props          | <code>ProfileCard</code> , <code>ProfileGrid</code> |
| Components as reusable building blocks | Making the card generic, not hard-coded             |
| One-way data flow                      | Passing profile objects downward                    |

---

**3 . Requirements**

| ID  | Requirement                                                                                                                                             |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| R-1 | <b>File structure</b> must contain <code>App.jsx</code> , <code>ProfileCard.jsx</code> , <code>profiles.js</code> , and <code>index.jsx</code> (entry). |
| R-2 | Declare an <b>array of at least 3 objects</b> in <code>profiles.js</code> ; each object matches the table above.                                        |
| R-3 | Create a reusable <b><code>ProfileCard</code> component</b> that receives a single profile object via props and renders the UI.                         |
| R-4 | Create a <b><code>ProfileGrid</code> (or <code>App</code>) component</b> that maps over the array and renders a grid of cards.                          |

---

| ID  | Requirement                                                                                                                             |
|-----|-----------------------------------------------------------------------------------------------------------------------------------------|
| R-5 | Use <b>semantic HTML</b> inside JSX ( <code>&lt;article&gt;</code> , <code>&lt;img&gt;</code> , <code>&lt;h2&gt;</code> , etc.).        |
| R-6 | Apply <b>basic CSS</b> (inline style or external file) so the cards sit in a neat grid, have subtle borders, and the avatar is rounded. |
| R-7 | No class components, hooks, or state yet—this task focuses strictly on <i>props</i> and <i>rendering</i> .                              |
| R-8 | Lint-/compile-error-free when run with <code>npm create vite@latest</code> → React template (or CRA if you prefer).                     |

#### 4 . Stretch Goals (Optional)

1. **Hover interaction** – on hover, elevate the card (`box-shadow`) and slightly enlarge the avatar.
2. **Conditional rendering** – if a profile object is missing a bio, display “No bio provided”.
3. **Prop-Types** – add runtime type-checking with the `prop-types` package.

#### 5 . Handoff Checklist

- ☐ Repository named `react-profile-card-YOURNAME`
- ☐ `README.md` with setup commands (`npm install`, `npm run dev`)
- ☐ Screenshots or short GIF of the finished grid
- ☐ Code contains **meaningful comments** that explain *why* each component exists

**Submission format:** zip the repo or push to your classroom Git provider before the next lecture.

Happy coding! 🌱
